**Viral infection during pregnancy has been correlated with increased frequency of autism spectrum disorder (ASD) in offspring. This observation has been modeled in rodents subjected to maternal immune activation (MIA). The immune cell populations critical in the MIA model have not been identified. Using both genetic mutants and blocking antibodies in mice, we show that retinoic acid receptor–related orphan nuclear receptor  $\gamma$ t (ROR $\gamma$ t)–dependent effector T lymphocytes [e.g., T helper 17 (T<sub>H</sub>17) cells] and the effector cytokine interleukin-17a (IL-17a) are required in mothers for MIA-induced behavioral abnormalities in offspring. We find that MIA induces an abnormal cortical phenotype, which is also dependent on maternal IL-17a, in the fetal brain. Our data suggest that therapeutic targeting of T<sub>H</sub>17 cells in susceptible pregnant mothers may reduce the likelihood of bearing children with inflammation-induced ASD-like phenotypes**

Several studies have suggested that viral infection of women during pregnancy correlates with an increased frequency of ASD in the offspring (1–6). In the rodent maternal immune activation model of this phenomenon (7), offspring from pregnant mice infected with virus or injected intraperitoneally with synthetic dsRNA [poly(I:C)], a mimic of viral infection, exhibit behavioral symptoms reminiscent of ASD: social deficits, abnormal communication and repetitive behaviors (8). T<sub>H</sub>17 cells are responsible for immune responses against extracellular bacteria and fungi, and their dysregulation is thought to underlie numerous inflammatory and autoimmune diseases (9), such as asthma, rheumatoid arthritis, psoriasis, inflammatory bowel disease (IBD) and multiple sclerosis. The transcription factor retinoic acid receptor–related orphan nuclear receptor gamma t (ROR $\gamma$ t) is expressed in several cell types in the immune system. It is a key transcriptional regulator for the development of T<sub>H</sub>17 cells, as well as  $\gamma\delta$  T cells and innate lymphoid cells (such as ILC3) that express T<sub>H</sub>17 cell-like cytokines, in both humans and mice (10–13).

T<sub>H</sub>17 cells and their cytokine mediators have been suggested to have a role in ASD. For example, elevated levels of IL-17a, the predominant T<sub>H</sub>17 cytokine, have been detected in the serum of a subset of autistic children (14, 15). A genome-wide copy number variant (CNV) analysis identified *IL17A* as one of many genes enriched in autistic patients

(16). Similarly, in the MIA mouse model, CD4<sup>+</sup> T lymphocytes from affected offspring produced higher levels of IL-17a upon in vitro activation (17, 18). While these data suggest that T<sub>H</sub>17 cells may be involved in ASD patients, whether T<sub>H</sub>17 cells are the specific immune cell population that is necessary for MIA phenotypes is unknown. Here we show that maternal ROR $\gamma$ t-expressing pro-inflammatory T cells, a major source of IL-17a, are required in the MIA model for induction of ASD-like phenotypes in offspring. Consistent with this notion, antibody blockade of IL-17a activity in pregnant mice protected against the development of MIA-induced behavioral abnormalities in the offspring. Importantly, we also found atypical cortical development in affected offspring, and this abnormality was rescued by inhibition of maternal T<sub>H</sub>17/IL-17a pathways.

## Elevated fetal brain IL-17Ra mRNA follows increased maternal IL-17a in MIA

Pregnant mothers injected with poly(I:C) on embryonic day 12.5 (E12.5) had strong induction of serum cytokines IL-6, tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interferon- $\beta$  (IFN- $\beta$ ) and IL-1 $\beta$  at 3h, compared with PBS-injected control dams (Fig. 1A and fig. S1, A to C). Additionally, poly(I:C) injection resulted in a strong increase of serum IL-17a at E14.5 (Fig. 1B). On the other hand, poly(I:C) did not affect the levels of the anti-inflammatory cytokine IL-10 in the serum nor in pla-

centa and decidua extracts (fig. S1D). It was previously shown that the pro-inflammatory effector cytokine IL-6, a key factor for T<sub>H</sub>17 cell differentiation (19), is required in pregnant mothers for MIA to produce ASD-like phenotypes in the offspring (7). We found that poly(I:C) injection into pregnant dams lacking IL-6 (IL-6 KO) failed to increase the serum levels of IL-17a at E14.5, consistent with IL-6 acting upstream of IL-17a. Conversely, recombinant IL-6 injections into wild-type (WT) mothers were sufficient to induce IL-17a levels comparable to those of poly(I:C)-injected WT mothers (fig. S1E). Placenta- and decidua-associated mononuclear cells, isolated from poly(I:C)-treated animals at E14.5 and cultured for 24 hours, expressed similar amounts of IL-6 mRNA compared to PBS controls (Fig. 1C). In contrast, IL-17a mRNA expression in these cells was strongly up-regulated by poly(I:C) injection (Fig. 1D). This increase in mRNA expression was correlated with enhanced secretion of IL-17a by placenta- and decidua-associated mononuclear cells from poly(I:C)-treated dams (Fig. 1E), upon *ex vivo* stimulation with phorbolmyristate acetate (PMA) and ionomycin that mimics T cell receptor (TCR) activation. IL-17a induction was specific to the placenta and decidua, as small intestine mononuclear cells from poly(I:C)-treated pregnant dams did not secrete more IL-17a than those from PBS-treated controls (fig. S1F).

We also observed that expression of the IL-17a receptor subunit A (IL-17Ra), but not subunit C (IL-17Rc), mRNA was strongly augmented in the fetal brain upon induction of MIA (Fig. 1, F and G). By *in situ* hybridization, IL-17Ra mRNA was detected in the mouse cortex, and its expression was strongly up-regulated in E14.5 fetal brains following poly(I:C) injection of pregnant dams (Fig. 1, H and I). The *in situ* probe detecting endogenous expression of IL-17Ra was specific, as it did not produce detectable signal in E14.5 fetal brain that lacks IL-17Ra (fig. S2).

### **Maternal IL-17a promotes abnormal cortical development in offspring**

We next investigated if pathological activation of the IL-17 pathway in pregnant mothers affects fetal brain development and subsequently contributes to the ASD-like behavioral phenotypes in offspring. To test this hypothesis, we pretreated pregnant mothers with isotype control or IL-17a blocking antibodies before injecting them with PBS or poly(I:C) (fig. S3). We then examined cortical development in the fetus for the following reasons: (i) Poly(I:C) injection of mothers increases IL-17Ra expression in the cortex of the fetal brain (Fig. 1, H and I); (ii) Cortical development starts approximately at E11 (20), which aligns well with the time points of potential fetal exposure to MIA (7); (iii) Disorganized cortex and focal patches of abnormal laminar cytoarchitecture have been found in the brains of ASD patients

(21, 22); and (iv) MIA has been shown to affect cortical development (23, 24). We analyzed cortical lamination, an orderly layered structure of the developing cortex, in fetal brains at E14.5 and E18.5 as well as in the adult brain using antibodies specific for proteins expressed in the cortex in a layer-specific manner (25): Special AT-rich sequence-binding protein 2 (SATB2) (26), T-brain-1 (TBR1) (27), and chicken ovalbumin upstream promoter transcription factor-interacting protein 2 (CTIP2) (28). MIA led to delayed expression of SATB2 at E14.5 compared with fetuses of control animals (Fig. 2, A and C). At E18.5, MIA resulted in a patch of disorganized cortical cytoarchitecture (Fig. 2, B and D to G) but did not affect cortical thickness of the fetal brains (Fig. 2H). This singular patch of disorganized cortex occurred at a similar medial-lateral position in a majority of E18.5 fetal brains (Fig. 2, E and G) derived from mothers injected with poly(I:C), but not PBS. The abnormal expression patterns of SATB2, TBR1 and CTIP2 were maintained in adult MIA offspring (fig. S4). Importantly, normal expression of these cortical layer-specific markers, as well as laminar cortical organization, were largely preserved in the offspring of poly(I:C)-injected mothers pretreated with IL-17a blocking antibody (Fig. 2, A to D, and fig. S4).

Pretreatment with IL-17a blocking antibody also suppressed the MIA-mediated increase in IL-17Ra mRNA expression in fetal brain at E14.5 (Fig. 1F). This suppression was accompanied by a reduction in maternal serum IL-17a (Fig. 1B), indicating that the upregulation of IL-17Ra mRNA in fetal brains requires maternal IL-17a signaling. Of note, IL-17a antibody blockade of the IL-17a/IL-17Ra signaling pathway did not result in a concomitant increase of the serum IL-10 levels, and IL-17a mRNA expression was not detected in fetal brain at E14.5, regardless of poly(I:C) injection. Together, these data demonstrate that the maternal IL-17a-dependent pathway mediates disorganized cortical phenotypes in offspring following *in utero* MIA and suggest that this may be due to exposure of the fetus and its brain to increased levels of IL-17a.

### **Maternal IL-17a promotes ASD-like behavioral abnormalities in offspring**

We next tested the functional relevance of the maternal IL-17a pathway for MIA-induced ASD-like behavioral abnormalities in offspring (fig. S3). We first assessed MIA offspring for abnormal communication by measuring pup ultrasonic vocalization (USV) responses (29). Following separation from mothers, pups from poly(I:C)-injected mothers pretreated with IgG isotype control antibody emitted more USV calls than those from PBS-injected mothers (Fig. 3A), in agreement with previous studies (29, 30). Some studies have reported reduced USV calls upon MIA (8, 31), but these opposite effects may reflect differences in methodological ap-

proaches, including dose and number of exposures to poly(I:C) as well as timing of poly(I:C) administration. Altogether, these results indicate that MIA induces abnormal USV in offspring. Pretreating poly(I:C)-injected mothers with IL-17a blocking antibody resulted in offspring that emitted a similar number of USV calls as the pups from PBS-injected control mothers (Fig. 3A), demonstrating that IL-17a-mediated signaling events are necessary for the MIA-induced abnormal USV phenotype. As previously reported (7, 8), we found that prenatal exposure to MIA also caused social interaction deficits in adult offspring (Fig. 3B). This defect was fully rescued in offspring from poly(I:C)-injected mothers pretreated with IL-17a blocking antibody (Fig. 3B). Repetitive/perseverative behaviors are another core feature in ASD that we tested next in our experimental mice using the marble burying assay (32). Offspring from poly(I:C)-injected mothers displayed enhanced marble burying compared with offspring from PBS-injected mothers (Fig. 3C), consistent with previous studies (7, 29). Pretreatment with IL-17a blocking antibody of poly(I:C)-injected mothers rescued marble burying behavior in the offspring (Fig. 3C). Importantly, distinct behavioral phenotypes observed among different treatment groups were not due to differences in activity or arousal as total distances moved during the sociability or marble burying tests were indistinguishable (Fig. 3D). Moreover, different treatment groups displayed comparable gender ratios, litter sizes, and weights (fig. S5). Taken together, these data indicate that the IL-17a pathway in pregnant mice is crucial in mediating the MIA-induced behavioral phenotypes in offspring.

### **ROR $\gamma$ t expression in maternal T cells is required for ASD-like phenotypes in the MIA offspring.**

As ROR $\gamma$ t is a critical regulator of the IL-17a pathway (13), we next investigated the role of maternal ROR $\gamma$ t in MIA-induced behavioral phenotypes in offspring. Importantly, T<sub>H</sub>17 cells and IL-17a have been detected in the decidua as well as in the serum during pregnancy in humans (33–35). CD45<sup>+</sup> mononuclear cells, including CD4<sup>+</sup> T cells, isolated from placenta and decidua of immune-activated WT mothers, but not from immune-activated mothers lacking both ROR $\gamma$ t and the closely related ROR $\gamma$  isoform (ROR $\gamma$  KO), produced IL-17a upon ex vivo activation with PMA and ionomycin (fig. S6, A and B). Cells isolated from WT and ROR $\gamma$  KO mice secreted similar amounts of IFN- $\gamma$ , consistent with the specific effect of ROR $\gamma$ t on IL-17a expression (fig. S6C). In line with this observation, poly(I:C) treatment increased placenta/decidua-associated T<sub>H</sub>17 but not regulatory T (Treg) cells in pregnant dams, compared with PBS treatment (fig. S6D and E). ROR $\gamma$  KO mice lack ROR $\gamma$ / $\gamma$ t expression not only in CD4<sup>+</sup> T cells, but also in other lymphoid and non-immune system cells, and they

have defective development of secondary and tertiary lymphoid organs (36, 37). To determine if ROR $\gamma$ t function specifically in T cells mediates MIA-induced phenotypes, we bred ROR $\gamma$ t<sup>FL</sup> animals (fig. S7) to CD4-Cre mice to selectively inactivate *rorc(t)* in the T cells of pregnant mothers (ROR $\gamma$ t TKO) (38). In these animals, the functions of T<sub>H</sub>17 cells (CD4<sup>+</sup>ROR $\gamma$ t<sup>+</sup> cells) and other ROR $\gamma$ t-expressing  $\alpha\beta$ T cells are inhibited, but there is no effect in ROR $\gamma$ t-expressing innate (or innate-like) immune cells, including  $\gamma\delta$ T, lymphoid tissue-inducer (LTi) cells, and innate lymphoid cells type 3 (ILC3) (11, 12), as well as in ROR $\gamma$ -expressing non-lymphoid cells. We found that ROR $\gamma$ t TKO mothers failed to produce IL-17a even after poly(I:C) injection (fig. S6F). Importantly, poly(I:C)-induced malformation of the cortex was prevented in offspring from ROR $\gamma$ t TKO mothers (Fig. 4, A and B), similar to anti-IL-17a treatment (Fig. 2, B and D). Moreover, we found that prenatal exposure to MIA increased USV calls in pups derived from WT or ROR $\gamma$ t HET mothers, but offspring of ROR $\gamma$ t TKO mothers had normal USV behavior (Fig. 4C). T cell-specific deletion of maternal ROR $\gamma$ t also abrogated the MIA-induced social interaction deficit and excessive marble burying in offspring (Fig. 4, D and E). These results were not due to general activity defects in the offspring of WT, ROR $\gamma$ t HET, or TKO mothers (Fig. 4F). Since these offspring were derived from mating ROR $\gamma$ t WT/HET/TKO female with WT male mice, they all carried at least one copy of functional ROR $\gamma$ t. Therefore, the rescue of MIA-induced phenotypes observed in the offspring of ROR $\gamma$ t TKO mothers was not likely due to the lack of T<sub>H</sub>17 cells in the offspring. Taken together, these data indicate that maternal CD4<sup>+</sup> T lymphocytes expressing ROR $\gamma$ t (i.e., T<sub>H</sub>17 cells) are necessary for the MIA-mediated expression of cortical abnormalities and three ASD-like behaviors modeled in mouse offspring.

### **IL-17a administration to the fetal brain promotes abnormal cortical development and ASD-like behavioral phenotypes**

To determine if IL-17a acts on receptors in the mother or the fetus to induce the MIA phenotype, we injected poly(I:C) into IL-17Ra WT, HET or KO mothers that had been bred to IL-17Ra WT or HET males (39). Removing one or both copies of *il17ra* in the mother was sufficient to rescue the MIA-induced sociability deficit in offspring regardless of their genotypes (fig. S8A). Moreover, we found that reduced expression of maternal IL-17Ra in *il17ra* HET mothers led to reduced serum IL-17a in poly(I:C)-treated mothers (fig. S8B). Thus, it is difficult, if not impossible, to test the functional significance of the IL-17Ra in offspring with a full germline *il17ra* KO without affecting maternal T<sub>H</sub>17 cell activity. To circumvent this problem, we asked if increasing IL-17Ra activity in the offspring, by introducing IL-17a directly into

the fetal brain in the absence of maternal inflammation, would be sufficient to induce MIA phenotypes. Injection of recombinant IL-17a protein into the ventricles of the fetal brain at E14.5 in the absence of MIA (Fig. 5A) led to the appearance of disorganized cortical patches in a similar location to those induced by MIA (Fig. 5, B to E). Unlike poly(I:C) injection, however, intra-ventricular injection of IL-17a resulted in thinned cortical plates at the medial but not lateral part of the brain (fig. S9). This effect may reflect differences in the levels or types of inflammation associated with poly(I:C) versus IL-17a injections or the time points at which poly(I:C) (E12.5) and IL-17a (E14.5) were administered. We also found that, compared with sham injection, IL-17a injections led to an enhanced USV phenotype, social approach deficit and increased marble burying behavior, all similar in magnitude to that observed in MIA-exposed offspring (Fig. 5, F to H). These behavioral abnormalities were not due to group differences in mobility (Fig. 5I). Importantly, neither cortical disorganization nor enhanced USV phenotypes were observed following IL-17a injections into the ventricles of IL-17Ra KO fetuses or upon IL-6 injections into WT fetal brains (fig. S10, A to C), suggesting that IL-17a, but not IL-6, acts directly in the fetal brain to induce these phenotypes. Of note, in agreement with previous reports (7, 40), IL-6 injection into pregnant WT mothers was sufficient to produce MIA-associated behavioral (enhanced USV) and cortical phenotypes in the offspring (fig. S10, D to F). Importantly, pretreatment of pregnant mothers with anti-IL-17a blocking antibody prevented the phenotypes induced by maternal IL-6 injection (fig. S10, D to F). Lastly, IL-17a injection into brains of fetuses from poly(I:C)-injected IL-6 KO mothers was sufficient to elicit increased pup USVs compared with PBS-injected controls (fig. S10G). These data collectively demonstrate that activation of the IL-17Ra pathway in the fetal brain, induced by intra-ventricular injection of IL-17a into the fetus or by intra-peritoneal injection of poly(I:C) or IL-6 into pregnant mothers, results in MIA-associated phenotypes in the offspring.

### Therapeutic treatment with anti-IL-17a blocking antibody in pregnant dams ameliorates MIA-associated behavioral abnormalities

Our results suggest that pathological activation of the T<sub>H</sub>17 cell/IL-17 pathway during gestation in mothers with some inflammatory conditions may alter fetal brain development and contribute to the ASD-like behavioral phenotypes in offspring (fig. S11). T<sub>H</sub>17 cells require ROR $\gamma$ t for their differentiation and exert their functions by secreting multiple cytokines, including IL-17a. Abrogation of ROR $\gamma$ t expression in maternal  $\alpha\beta$  T cells or blockade of the IL-17 pathway in pregnant dams resulted in the complete rescue of cortical developmental abnormalities and ASD-like behavioral phe-

notypes in offspring in the MIA rodent model. Thus, ROR $\gamma$ t and T<sub>H</sub>17 cells (as well as their cytokines) may serve as good therapeutic targets to prevent the development of ASD phenotypes in the children of susceptible mothers. To further test this idea, we administered anti-IL-17a antibody to pregnant mice in a time window following MIA induction (Fig. 6). We injected pregnant mothers with PBS or poly(I:C) at E12.5, followed by injection of IgG isotype control or anti-IL-17a blocking antibody at E14.5, when the delayed expression of SABB2 manifests in MIA-exposed fetal brains (Fig. 2, A and C). Compared to PBS injection followed by control antibody treatment, poly(I:C) injection followed by anti-IL-17a antibody administration partially rescued USV and marble burying phenotypes (Fig. 6, B and D). However, MIA-induced social interaction deficits were not corrected (Fig. 6C). These effects were not due to group differences in mobility (Fig. 6E). Thus, treating pregnant mothers with anti-IL-17a after MIA can correct some of the ASD-like features, but pretreatment with anti-IL-17a antibody may have greater therapeutic potential.

### Conclusions

Our results identify a specific maternal immune cell population that may have direct roles in inducing ASD-like phenotypes by acting on the developing fetal brain. These findings raise the possibility that modulation of the activity of a cytokine receptor, IL-17Ra, in the central nervous system can influence neuronal development, with implications as to specification of neuronal cell types and their connectivity. Furthermore it is worthwhile to note that the loss of certain genes that induce ASD-like phenotypes were also found with defects in cortical lamination (41, 42). These observations raise the possibility that some genetic and environmental factors that have roles in the etiology of ASD function by way of similar physiological pathways. A related question is whether IL-17Ra signaling has a normal physiological function in the fetal and adult brain, especially given the structural similarities observed between the IL-17 family cytokines and neurotrophin proteins (e.g., nerve growth factor) (43, 44). Elucidating further downstream pathways of maternal IL-17a-producing T cells, both in MIA-mothers and their offspring, will likely yield a better understanding of the mechanisms by which inflammation *in utero* contributes to the development of neurodevelopmental disorders such as ASD and may, additionally, provide insights into the roles of cytokine receptors in the central nervous system.

#### ACKNOWLEDGMENTS

We thank E. Kurz, D. Montgomery, and Y. Cai for assistance with experiments and thank J. Koll for providing the *i17r* KO mouse line, which was originally developed by Amgen. The *i17ra*<sup>KO</sup> line will be available from D.R.L. under a material transfer agreement with Amgen. We also thank M. Sellars for critical reading of the manuscript. The data presented in this paper are tabulated in the main text and in the supplementary materials. This work was supported by the Simons Foundation Autism Research Initiative (D.R.L.), the Simons Foundation to the Simons Center for the Social Brain at MIT (Y.S.Y. and G.B.C.), Robert Buxton (G.B.C.), the National Research Foundation of Korea grants MEST-35B-2011-1-E00012 (S.K.) and NRF-2014R1A1A1006089 (H.K.), the Crohn's and Colitis Foundation of America grant 329388 (S.V.K.), the Smith Family Foundation (J.R.H.), Alzheimer's Association MNIRGDP-12-258900 (C.A.H.), NARSAD 21069 (C.A.H.), and the National Institutes of Health grants F31NS083277 (H.W.), R00DK091508 (J.R.H.), R01NS086933 (C.A.H.), and the Howard Hughes Medical Institute (D.R.L.). D.R.L. and J.R.H. are inventors on a patent application filed by New York University, related to the studies reported here

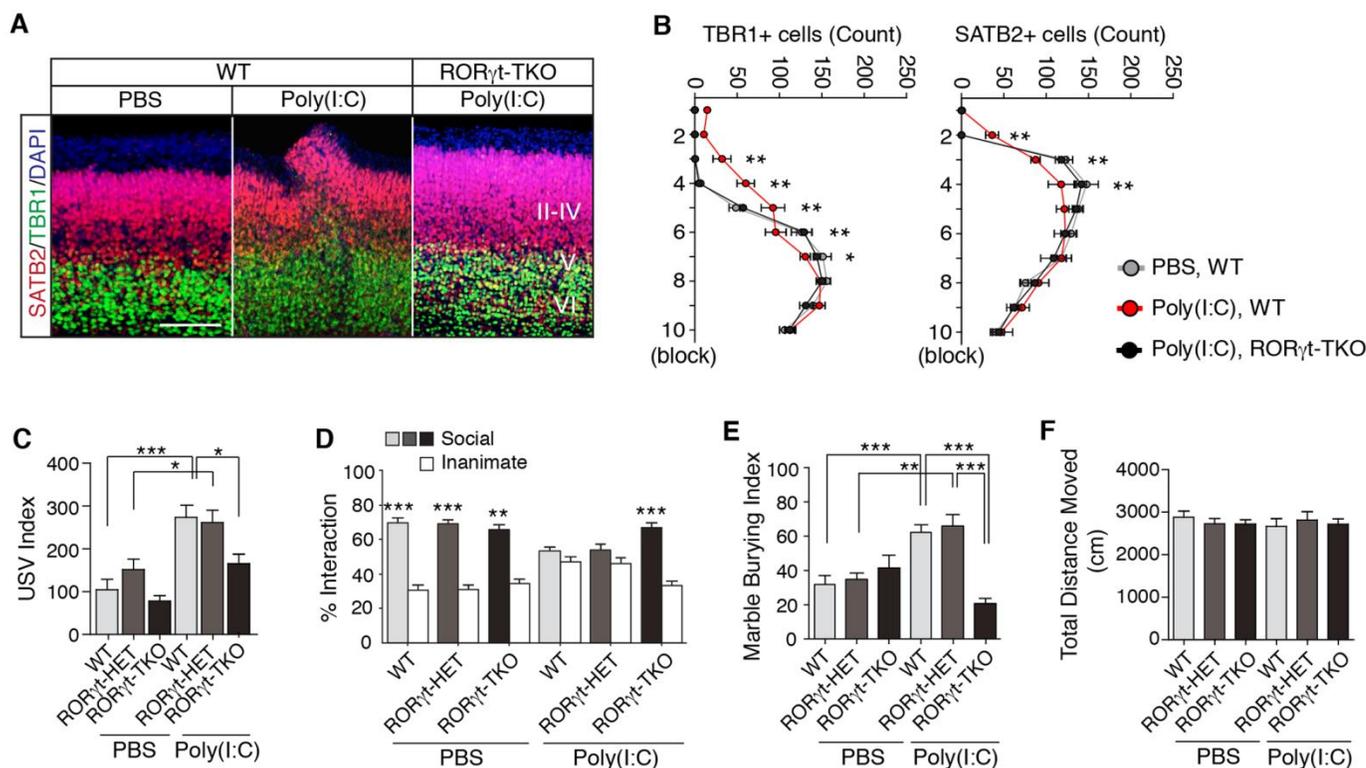

**Fig. 1. IL-17a increase in mothers subjected to MIA leads to elevated IL-17Ra mRNA expression in the offspring.** (A) Serum concentrations of IL-6 ( $n = 3-5$  mice per group, 2 independent experiments) at 3 or 24 hours after PBS or poly(I:C) injection into pregnant dams at E12.5. (B) Serum concentrations of maternal IL-17a ( $n = 4-8$  mice per group, 2 independent experiments) at E14.5 in PBS- or poly(I:C)-injected mothers, pretreated with or without IL-17a blocking antibodies. (C and D) Relative IL-6 (C) and IL-17a (D) mRNA expression in cells isolated from placenta/decidua of PBS- or poly(I:C)-treated mothers at E14.5 and cultured in vitro for 24 hours. The results are representative of three independent experiments. For each probe set, relative mRNA expression of one biological replicate from PBS-treated dams was set at 1. Real-time PCR analysis of relative expression of indicated genes compared to the level of Gapdh in cells from PBS-treated dams. (E) Supernatant concentrations of IL-17a from ex vivo cultured mononuclear cells, isolated from placenta/decidua of PBS- or poly(I:C)-treated pregnant dams. Stim refers to PMA and Ionomycin stimulation. (F and G) Relative IL-17Ra (F) and IL-17Rc (G) mRNA levels in E14.5 male fetal brain, derived from PBS- or Poly(I:C)-injected mothers, pretreated with isotype control (Cont) or IL-17a blocking antibodies (anti-IL-17a). The relative mRNA fold change, compared to the PBS and Cont-treated group, is plotted on the y-axis ( $n = 7$  (PBS, Cont),  $n = 7$  (PBS, anti-IL-17a),  $n = 7$  (Poly(I:C), Cont),  $n = 7$  (Poly(I:C), anti-IL-17a); from 2-3 independent experiments). (H) In situ hybridization with an IL-17Ra RNA probe in E14.5 male fetal brains derived from PBS- or poly(I:C)- injected mothers. Images are representative of four independent experiments. (I) Relative signal intensity for images shown in (H). Scale bar represents 100  $\mu\text{m}$ . (A, B, E, F and G) One-way ANOVA with Tukey post-hoc tests. (C, D and I) Student's  $t$  test.  $**P < 0.01$ . Graphs show mean  $\pm$  SEM.

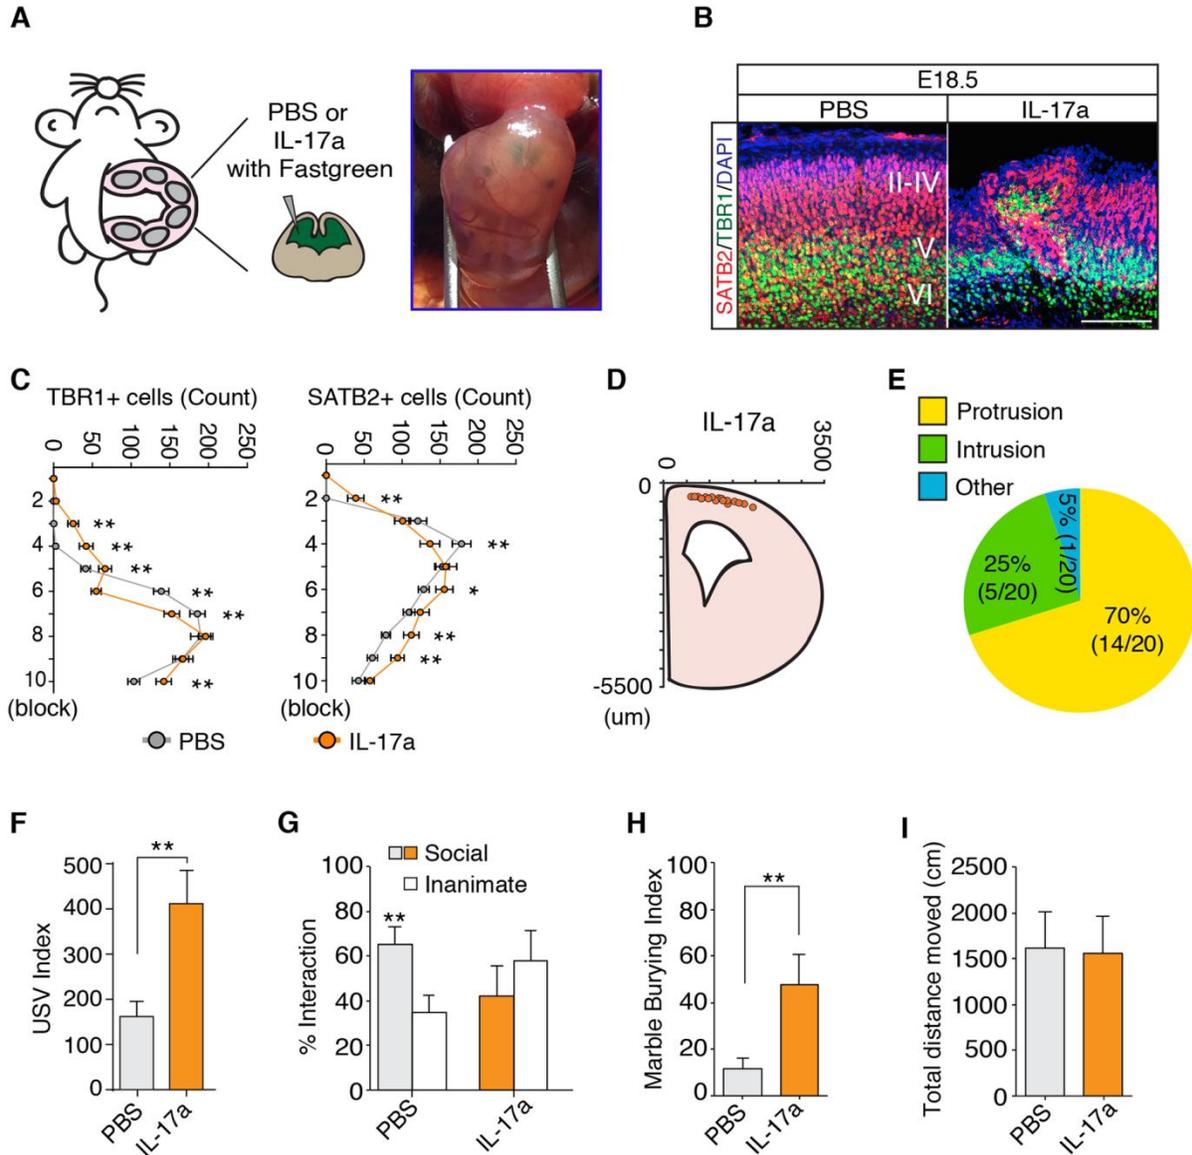

**Fig. 2. Fig. 2. The IL-17a pathway promotes abnormal cortical development in the offspring of pregnant dams following MIA. (A)** Immuno-fluorescence staining of SATB2 (a marker of postmitotic neurons in superficial cortical layers) in E14.5 male fetal brain, derived from PBS- or poly(I:C)-injected mothers, pretreated with isotype control (Cont) or IL-17a blocking antibodies (anti-IL-17a). (MZ: marginal zone, CP: cortical plate, SP: subplate, SVZ: subventricular zone, VZ: ventricular zone). **(B)** Staining of SATB2 and TBR1 (a marker restricted to deeper cortical layers) in E18.5 male fetal brains from animals treated as in (A). II-IV, V and VI refer to different cortical layers. **(C)** Quantification of SATB2 intensity in the cortical plate of E14.5 fetal brains ( $n = 8$  (PBS, Cont),  $n = 8$  (PBS, anti-IL-17a),  $n = 8$  (Poly(I:C), Cont),  $n = 8$  (Poly(I:C), anti-IL-17a), 3 independent experiments). **(D)** Quantification of TBR1 and SATB2 positive cells in a  $300 \times 300 \mu\text{m}^2$  region of interest (ROI) centered on the malformation in the cortical plate of E18.5 fetal brains ( $n = 20$  (PBS, Cont),  $n = 20$  (PBS, anti-IL-17a),  $n = 24$  (Poly(I:C), Cont),  $n = 20$  (Poly(I:C), anti-IL-17a), 5 independent experiments). **(E)** The spatial location of the cortical patch in E18.5 male fetal brains from poly(I:C)-injected mothers pretreated with control antibodies ( $n = 20$  (Poly(I:C), Cont)). **(F)** The disorganized patches of cortex observed in fetuses from poly(I:C)-injected mothers were categorized into groups based on morphology: Protrusions, intrusions or other abnormal patterns and their representative images are shown. **(G)** Percentage of the cortical patches in each category ( $n = 24$  (Poly(I:C), Cont)). **(H)** Thickness of the cortical plate in E18.5 fetal brains, derived from PBS- or poly(I:C)-injected mothers, pretreated with isotype control or IL-17a blocking antibodies ( $n = 20$  (PBS, Cont),  $n = 20$  (PBS, anti-IL-17a),  $n = 20$  (Poly(I:C), Cont),  $n = 20$  (Poly(I:C), anti-IL-17a), 5 independent experiments). (A, B and F) Scale bar represents  $100 \mu\text{m}$ . One-way ANOVA (C and H) and Two-way ANOVA (D) with Tukey post-hoc tests.  $**P < 0.01$  and  $*P < 0.05$ . Graphs show mean  $\pm$  SEM.

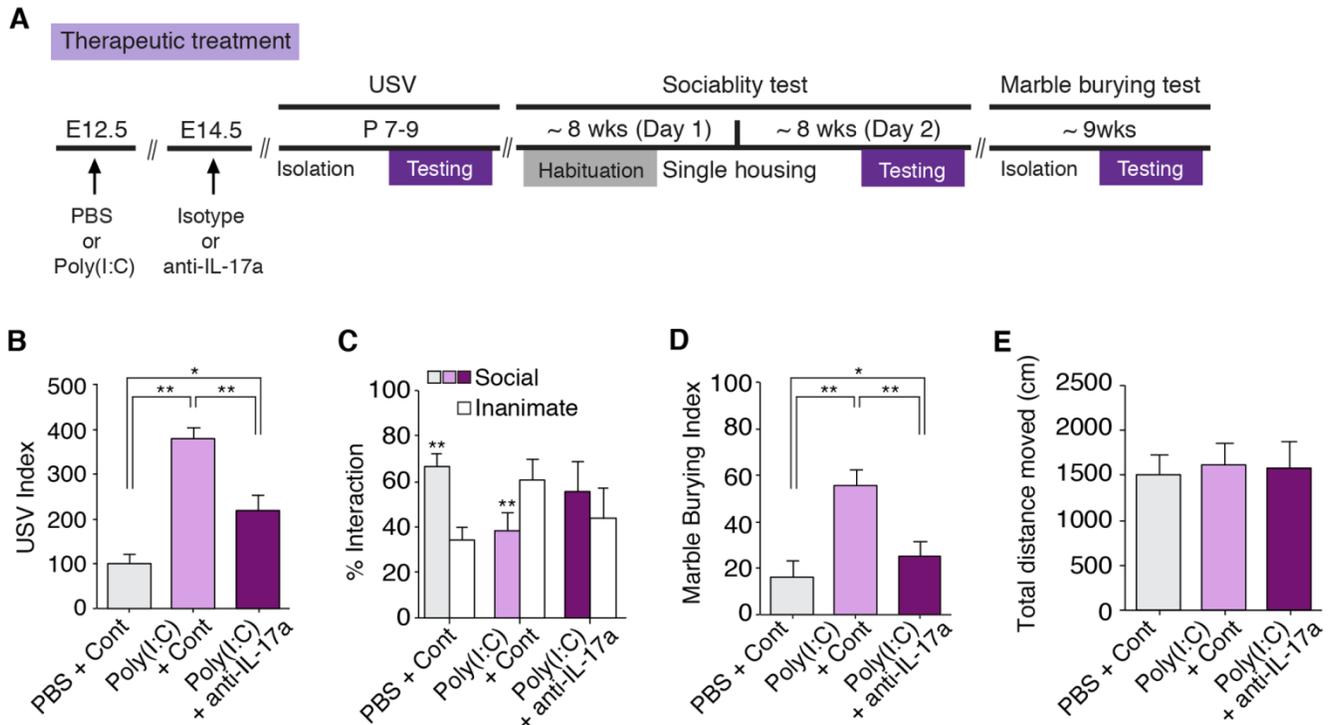

**Fig. 3. Fig. 3. The IL-17a pathway promotes ASD-like phenotypes in the MIA offspring.** (A) Ultrasonic vocalization (USV) assay. At P9, pups from the indicated experimental groups were separated from their mothers to elicit USV calls. The number of pup calls is plotted on the y-axis ( $n = 25$  (PBS, Cont),  $n = 28$  (PBS, anti-IL-17a),  $n = 38$  (Poly(I:C), Cont),  $n = 34$  (Poly(I:C), anti-IL-17a); from 6-7 independent experiments. (B) Social approach behavior. Graphed as a social preference index (% time spent investigating social or inanimate stimulus out of total object investigation time) ( $n = 15$  (PBS, Cont),  $n = 15$  (PBS, anti-IL-17a),  $n = 16$  (Poly(I:C), Cont),  $n = 20$  (Poly(I:C), anti-IL-17a); from 6-7 independent experiments. (C) Marble burying behavior. Percentage of the number of buried marbles is plotted on the y-axis ( $n = 15$  (PBS, Cont),  $n = 15$  (PBS, anti-IL-17a),  $n = 15$  (Poly(I:C), Cont),  $n = 20$  (Poly(I:C), anti-IL-17a); from 6-7 independent experiments. (D) Total distance traveled during social approach behavior. (A, C and D) One-way ANOVA with Tukey post-hoc tests. (B) Two-way ANOVA with Tukey post-hoc tests.  $**P < 0.01$  and  $*P < 0.05$ . Graphs show mean  $\pm$  SEM.

**Fig. 4. ROR $\gamma$ t expression in maternal T cells is required for manifestation of ASD-like phenotypes in the MIA model.** (A) SATB2 and TBR1 staining in the cortex of E18.5 fetal brains following MIA induction with poly(I:C) in mothers with the indicated genotypes. II-IV, V and VI refer to different cortical layers. Images are representative of three independent experiments. Scale bar represents 100  $\mu$ m. (B) Quantification of TBR1 and SATB2 positive cells in a 300x300  $\mu$ m<sup>2</sup> ROI centered on the malformation in the cortical plate of E18.5 male fetal brains ( $n = 6$  (PBS, WT),  $n = 6$  (Poly(I:C), WT),  $n = 6$  (Poly(I:C), ROR $\gamma$ t-TKO)). (C) Number of ultrasonic vocalizations (USVs) emitted by P9 pups. Total USVs emitted during test period (3 min) are plotted on the y-axis ( $n = 16, 18$  and  $15$  offspring from PBS-treated WT, ROR $\gamma$ t HET and ROR $\gamma$ t TKO mothers;  $n = 15, 11$  and  $28$  from poly(I:C)-treated WT, ROR $\gamma$ t HET and ROR $\gamma$ t TKO mothers); data from 4-7 independent dams. (D) Social approach behavior is graphed as a social preference index (% time spent investigating social or inanimate stimulus/ total exploration time for both objects). ( $n = 21, 15$  and  $15$  adult offspring from PBS-treated WT, ROR $\gamma$ t HET and ROR $\gamma$ t TKO mothers;  $n = 36, 15$  and  $21$  from poly(I:C)-treated WT, ROR $\gamma$ t HET and ROR $\gamma$ t TKO mothers); data from 4-7 independent dams. (E) Marble burying behavior is graphed as the percentage of buried marbles. ( $n = 14, 19$  and  $15$  adult offspring from PBS-treated WT, ROR $\gamma$ t HET and ROR $\gamma$ t TKO mothers;  $n = 32, 15$  and  $25$  from poly(I:C)-treated WT, ROR $\gamma$ t HET and ROR $\gamma$ t TKO mice per group); data from 4-7 independent dams. (F) Total distance moved by offspring tested for social behavior and marble burying. ROR $\gamma$ t HET and ROR $\gamma$ t TKO refer to ROR $\gamma$ <sup>Neo/+</sup>; CD4-Cre/+ and ROR $\gamma$ <sup>FL</sup>/ROR $\gamma$ <sup>Neo</sup>; CD4-Cre/+, respectively. (C) One-way ANOVA with Holm-Sidak post-hoc tests. (B and D) Two-way ANOVA with Tukey post-hoc tests. (E and F) One-way ANOVA with Tukey post-hoc tests. \*\*\* $P < 0.001$ , \*\* $P < 0.01$  and \* $P < 0.05$ . Graphs show mean  $\pm$  SEM.

**Fig. 5. IL-17a administration to the fetus promotes abnormal cortical development and ASD-like behavioral phenotypes.** (A) Schematic diagram of the experimental method. Each embryo was injected intraventricularly at E14.5 with PBS or recombinant IL-17a protein mixed with Fastgreen dye. (B) SATB2 and TBR1 staining in the cortex of E18.5 male fetal brains treated as in (A). Images are representative of five independent experiments. (C) Quantification of TBR1 and SATB2 positive cells in a 300- $\mu$ m wide ROI corresponding to the region of the cortical plate containing the malformation in E18.5 male fetal brain ( $n = 20$  (PBS),  $n = 20$  (IL-17a)). (D) The spatial location of the disorganized cortical patch in E18.5 fetal brain ( $n = 20$  (IL-17a)). (E) Percentage of the cortical patches in each category ( $n = 20$  (IL-17a)). (F) Ultrasonic vocalization (USV) assay. The number of pup calls is plotted on the y-axis ( $n = 15$  (PBS),  $n = 17$  (IL-17a); from 5-6 independent dams per treatment). (G) Social approach behavior. Graphed as a social preference index (% time spent investigating social or inanimate stimulus out of total object investigation time) ( $n = 12$  (PBS),  $n = 18$  (IL-17a), from 5-6 independent experiments). (H) Marble burying behavior. Percentage of the number of buried marbles is plotted on the y-axis ( $n = 12$  (PBS),  $n = 18$  (IL-17a), from 5-6 independent experiments). (I) Total distance traveled during social approach test. (C) Two-way ANOVA with Tukey post-hoc tests. (F, H and I) Student's *t* tests. (G) One-way ANOVA with Tukey post-hoc test. **\*\*** $P < 0.01$ , **\*** $P < 0.05$ , and ns; not significant. Graphs show mean  $\pm$  SEM.

**Fig. 6. Therapeutic effects of blocking IL-17a signaling in pregnant dams.** (A) Schematic diagram of the experimental design. At E12.5, pregnant mothers were injected with PBS or poly(I:C) to induce MIA. Two days later (E14.5), the pregnant mothers were treated with isotype or anti-IL-17a blocking antibodies. At P7~P9, pups were separated from the mothers to measure USV calls. At ~8wks, male offspring were subjected to the social approach test and marble burying test. (B) Ultrasonic vocalization (USV) assay. The number of pup calls is plotted on the y-axis ( $n = 17$  (PBS + Cont),  $n = 17$  (Poly(I:C) + Cont),  $n = 27$  (Poly(I:C) + anti-IL-17a; from 3-4 independent dams per treatment). (C) Social approach behavior. Graphed as a social preference index (% time spent investigating social or inanimate stimulus out of total object investigation time) ( $n = 12$  (PBS + Cont),  $n = 10$  (Poly(I:C) + Cont),  $n = 17$  (Poly(I:C) + anti-IL-17a; from 3-4 independent dams per treatment). (D) Marble burying behavior. Percentage of the number of buried marbles is plotted on the y-axis ( $n = 12$  (PBS + Cont),  $n = 10$  (Poly(I:C) + Cont),  $n = 17$  (Poly(I:C) + anti-IL-17a; from 3-4 independent dams per treatment). (E) Total distance traveled during social approach behavior. (B, D and E) One-way ANOVA with Tukey post-hoc tests. (C) Two-way ANOVA with Tukey post-hoc test. \*\* $P < 0.01$  and \* $P < 0.05$ . Graphs show mean  $\pm$  SEM.

## The maternal interleukin-17a pathway in mice promotes autismlike phenotypes in offspring
